

Vision, Spiders & Time

David Pierre Leibovitz
February 15, 2011

15 February 2011

David Pierre Leibovitz (Carleton University)

Vision, Spiders & Time - 1

Summary

- How is vision perception related to imagination and planning
- What is the role of attention (saccades)
- Can smart spiders shed light on human cognition?
 - They have severe engineering restrictions
 - They they take a long time to think
 - How does that affect cognition
- I will relate spider time to practical matters
- Hopefully, you will also come to appreciate spiders as well 😊

Human Vision Like a Camera?

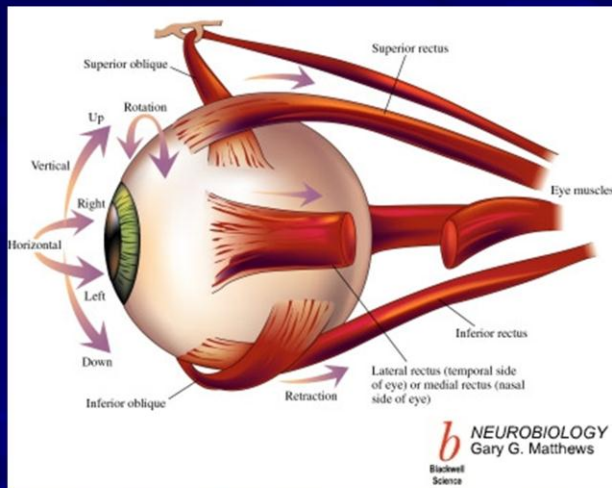

- Static Camera vs. Video
 - Do we process changes?
- Process entire scene or saccade/attend to others
- Is it process-interpret-act or a top-down/bottom-up iterative thing
- What about imagination?

Vision

- Movies @ 24hz (42ms/frame)
 - But flicker at higher rates?
- Major saccades @ 5hz (20-200ms/move)
 - Can miss

See: http://en.wikipedia.org/wiki/Flicker_fusion_threshold

Saccades

15 February 2011

David Pierre Leibovitz (Carleton University)

Time Matters - 5

Saccades	Major (Clinically observable)		Minor (Hard to observe)	
	Large	Small	Mini/Flick	Micro/Trem or
Angular Distance	>6.2°	6.2° - 1.2°	1.2° - 2'	40"
Occurrence	.05 - .3hz	Up to 5hz	40hz -	- 200hz
Time	200ms	20-200ms	10-20ms	<10ms
Reason	Head, Body Orientation Changes		View other features of object, next character grouping	Refresh Rod/Cone Signalling Extra Detail?

15 February 2011 David Pierre Leibovitz (Carleton University) Time Matters - 6

- The major/small saccades are the ones most people research or know about

Saccadic Eye Motion

- Major Saccades
 - Large Saccades
 - Enables the building up of a high resolution mental map from “interesting” parts of a scene
 - The fastest part of the human body (1000°/s).
- Microsaccades (20 arc seconds @ ~90Hz) serve to refresh image on rod and cone cells which respond to changes in luminance (otherwise a fixed stare would cause an image to slowly disappear)
 - It is possible that this also improves resolution
 - Jitter camera
 - 1 pixel camera
- During saccade, details are masked (mirror experiment). Motion of eye, blur of image nor time gap are perceived.
 - Can't see flash of light during saccade
 - Can't see object moved during saccade
 - However, masking stops if blur stops, i.e., when saccade follows a moving object. During a 1ms a “snapshot” can be taken (+250ms for later processing).
 - Suppressing (magnocellular) M-pathway responsible for motion responding to transient, high-velocity stimuli of low spatial frequency
 - Enhancing (parvocellular) P-pathway responsible for colour information
 - → tradeoff to differentially process changes over time due to motion
 - Optokinetic reflex – ability to follow (slower) motion with eyes fixed

15 February 2011 David Pierre Leibovitz (Carleton University) Time Matters - 7

• Selective suppression during saccades

• 1994, David C. Burr, et al. Selective suppression of the magnocellular visual pathway during saccadic eye movements. *Nature* 371(6), 511 – 513

• Fulton, James T., *Processes in Animal Vision* {online} {Corona Del Mar, CA. USA} Vision Concepts, {published 2000-08-01}, {revised 2000-08-01}, {cited 2000-08-01}. Available on the Internet: URL: <http://www.4colorvision.com>

• 1 pixel camera

• From <http://www.newscientisttech.com/article/dn10233-singlepixel-camera-could-simplify-imaging-.html>

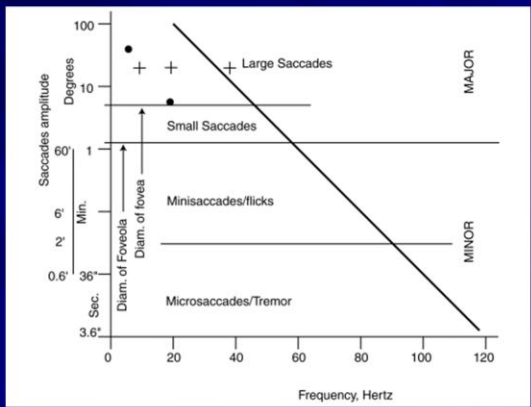

• One pixel over time

• Do not spend time throwing out (compressing) megapixel info, but just scan what is needed (compressed sensing – much like our peripheral/focal vision)

• Less memory and power (on compute intensive compression)

• Ability to engineer for infrared, ultraviolet & terahertz

• From: <http://www.dsp.ece.rice.edu/cscamera/>

15 February 2011

David Pierre Leibovitz (Carleton University)

Time Matters - 8

Jitter Camera

- Same as interlacing
- Related to micro-saccades
- Jitter (which doubles the sensing time) doubles perceptual resolution

15 February 2011

David Pierre Leibovitz (Carleton University)

Time Matters - 9

•Ben-Ezra, M., Zomet, A. & Nayar, S.K. (2004) Jitter Camera: High Resolution Video from a Low Resolution Detector. Proceedings of the 2004 IEEE Computer Society Conference on Computer Vision and Pattern Recognition (CVPR'04), Washington DC, II: 135-142, June 2004.

Visual Neglect

- In Visual Neglect, Patients can only see, or imagine half a scene.
- However, they can mentally rotate 180° and then imagine the other half (from the other perspective)
- This lends credence to the view that each side GENERATEs a view.

Scanning Tunneling Microscope

- Example of a 1 Pixel Camera
- Not even optical! Not limited by diffraction
- Highest resolution microscope (0.2 nm)

15 February 2011

Jumping Spider - *Portia labiata*

Portia labiata Male
F. Murphy, Selangor, Malaysia
15 February 2011

David Pierre Leibovitz (Carleton University)

- "1" pixel animal
- Cognitive Abilities
 - Scene building
 - Route planning/plotting (15-60 minutes)
 - Plan execution (several hours)
 - Goal may be invisible
 - Lure via adaptive mimicry
 - Tickle web to mimic other animals (or try different patterns)
 - Tactical Attack decisions
 - If prey carrying egg-sac, mount frontal assault (don't worry about spitting spider)
 - Else backwards assault
 - Top assault?
- Background
 - Jumping (venomous) spider
 - Eats other spiders
 - E.g., *Scytodes pallida*, a spitting (poison coated silk) spider that also eats other spiders
 - 600,000 neurons
 - Better vision than most mammals (but narrow)

Time Matters - 12

- Tactics/Strategic Planning???
- Route executions
 - Several hours (at this time, portions of scanned route are not visible)
 - Good memory
- *Portia* genus
 - makes up 20 out of 5000 species of jumping spiders (*Salticidae* or *salticids*)
 - Found in Africa, Australia & Asia
- More than hard-wired reflexes
 - Thinking
 - Planning
 - Trial-and-error learning
 - Attention span
 - Flexible behaviour
- Luring/deceiving (mimicking) other spiders away from their webs
 - Pluck rhythms on web to mimic a trapped insect or a hostile one
 - If prey encountered before, it will know what rhythms to use, else
 - Try out various patterns by trial and error

- Tickle lightly
- Strum vigorously
- Bob up and down
- Route Execution (great memory)
 - Avoid distraction
 - Avoid first wire (if wrong one)
 - Will give up on first wrong bend on wrong wire
- Other memory
 - If jump then swim strategy (vs swim all the way) is favoured, it will try this next time, Switch if not succesfull.
 - Dynamic strategy (plasticity)
 - Once a given prey has been killed, similar prey is found easier, less attuned to others
 - Selective attention
- References for this “Spider” section are

Spider Eyes

Most spiders have 8 eyes and poor vision. *Portia* sees very well – it jumps far and makes long circuitous routes to distant prey

- Postero-Lateral Eyes (PLE)
 - Wide Angle
 - Motion Sensing (Far)
 - **Blurry Vision**
- Postero Median Eyes (PME)
 - **Often tiny, Vestigial**
- Antero-Lateral Eyes (ALE)
 - Judging Distance
 - **Blurry Vision**
- Antero-Median Eyes (AME)
 - **Narrow Angle**
 - Excellent Vision
 - Colour
 - Swivel

15 February 2011

David Pierre Leibovitz (Carleton University)

Time Matters - 14

•Image from: <http://www.pbrc.hawaii.edu/microangela/jspider.htm>

•PME

•Sometimes is larger and covers off missing fields of view (and detects motion)

•“Focus” of presentation, will be on the front eyes only.

Spider Eyes – Fields of View

- ALE overlap enables accurate judgement of distance (binocular vision)
- AME do not overlap
 - Narrow telephoto systems

Time Matters - 15

•Image from Hill (1975,2006)

Acuity

■ *Portia* visual acuity is better than cats and pigeons

– Measured in angular resolution, not via light sensitivity

■ But slow...

15 February 2011

David Pierre Leibovitz (Carleton University)

Time Matters - 16

•Image from: Harland & Jackson (2000)

Spider – Field of View

Retina: several thousand photoreceptors

- Layered for different colours (green, blue, ultraviolet)
- Layer 1 (green) most acute, stacked for various focus distances. Swinging tube also helps
- **Fovea: several hundred photoreceptors ("1" pixel)**
- (human eye has 150 million photoreceptors; fovea less than 1% of retina but has 50% visual acuity)

15 February 2011

David Pierre Leibovitz (Carleton University)

Time Matters - 17

•Images from

•Spider: <http://www.amonline.net.au/spiders/toolkit/hairy/see.htm>

•Eye: Harland & Jackson (2000)

•With such a narrow field of view, Portia must scan its environment

Spider – Route Scanning & Planning

- Can see everything from the top of the dowel
 - 15-60 minutes to scan and plan (anticipatory maze learning)
 - Circuitous route (detour)
 - Simulate? its future movements or place memory?
 - Adaptive (goal directed) scanning vs. one-pixel camera (non-adaptive, entire scene)
 - Attend more to the correct route
 - Visually following tracks backwards from goal
 - Specific scanning patterns may be used for finding/resolving specific objects
 - Can find previously eaten prey faster
- Execution
 - Up to several hours to execute (in wild)
 - Lure could not be seen once down
 - Correct route chosen 75%
 - Even when further away
 - Even if longer
 - Even if both routes had lures, but one had a gap
 - Wrong route abandoned more often
 - On par with in complexity with vertebra
 - Select secondary objectives if needed?

15 February 2011

David Pierre Leibovitz (Carleton University)

Time Matters - 18

•Image from: Greenspan & Swinderen (2004)

•Many different setups used

•Eyes:

•4 pairs of simple (camera like) eyes

•1 pair of large principle eyes for acute vision & object detection

•2° field of view

(humans have 140°/eye horizontally, 90° vertically, 180° with both; fovea 2°-4°)

•30° (around and above) movement
190° of fovea with movement)

(humans have

•Fovea: 0.6°

•3 pairs of smaller secondary eyes for motion detection

•360° (around and above) field of view

•Seeing

•Area Examining

•Continuous back/forth, up/down sweeps

•“Spontaneous activity” even in absence of visual stimuli

•Object Scanning

•Restricts movement to object

•“Extended Retina”

•Body orientation also changed.

•Multiple routes in experimental design

•If it tried, difficulty did not affect correct choice

•“Confidence” used to discern if an attempt should be made

•Scanning is not just the building up of a (compressed) image. There simply aren't enough neurons to hold a single snapshot of the environment

Principles

- Time can be used to accumulate smaller bits of information into larger bits (scanning)
 - Scanning may be algorithmic
- However, to reduce scanning time (as compared to an actual 1 pixel camera) it must be adaptive, i.e. selective attention based on goals affected by memory
- Moreover, to reduce representation size, scanning must be done in conjunction with planning
 - It is possible that the “plan” is the representation of perception
 - We “see” and attend to affordances
- Perception and decision making (goal system) are part of a dynamic system and cannot be divorced
 - It is only when the timescales of both are similar that this is made apparent
 - Seeing the “big picture” is a more human example. Information needs to be synthesized in order to make good plans
- Even in humans, visual neglect shows that perception is goal oriented – a visuomotor system

One Pixel Camera

- Compressive Imaging/Sensing
 - Rather than take mega-pixel images and then compress (which is extremely resource intensive), build up your image smartly
 - Like our saccadic system?
 - Compressive classification
 - What we know (possible classifications) can influence what we are looking for, i.e., look quickly for distinctive salient features, look more at discriminants
 - Scanning is
 - Goal directed perception
 - Single pixel can be extremely specialized (sensitive, terahertz)
- Initial designs are not adaptive (no memory).
 - Quick scans of slowly (temporal & spatial) changing areas, more detailed elsewhere

Compression vs. Integration

- Top Row
 - 64x64 bit image with various wavelet compressions (throwing data out)
- Bottom Row
 - 320x240 DMD with various random samplings

- Existing system quite dumb. Previous sample (pixel) does not direct next one.
- → Leads to cognitive/dynamic systems
- Does it take longer to reduce a mega pixel image to an internal representation than to build one up pixel by pixel?
